

## BLOCK NONCE #2: Dependency Injection

### What?

Dependency Injection (DI) is a design pattern where an object receives its dependencies from an external source rather than creating them itself. It is like giving your code a toolbox instead of making it build its own tools.

### Why?

**Decouples components** – making it way easier to swap parts without breaking everything.

**Improves testability** - you can inject fake dependencies (mocks or stubs) when testing.

### How?

```
struct WalletService {
    provider: BlockchainProvider, // Without DI
}
impl WalletService {
    fn new() -> Self {
        WalletService {
            provider: BlockchainProvider::connect() // Hard-Coded dependency
        }
    }
}
```

Testing WalletService is difficult - you would need a real blockchain in your test....

```
struct WalletServiceDI<'a> {
    provider: &'a dyn BlockchainProviderTrait, // With DI
}
impl<'a> WalletServiceDI<'a> {
    fn new(provider: &'a dyn BlockchainProviderTrait) -> Self {
        WalletServiceDI { provider } // The provider is passed in
    }
}
```

Now you can simply use a mock blockchain and only test the behavior of WalletService.

**TIP** 💡 It can also be optional - give the user the ability to provide the dependencies, but allow them to pass None to get the default dependency.
