

BLOCK NONCE #7: Making Peace With Snapshot Tests

What?

Snapshot tests - although not ideal - are sometimes useful, like when testing the gas cost of a fixed transaction.

Why?

When snapshot tests break, the new correct hard-coded values are often already known — the computer just printed them! So why should we fix them manually?

How?

All rise for the **expect-test** crate 🎉 — from now on, hard-coded values fix themselves with this magic command: `UPDATE_EXPECT=1 cargo test`.
Instead of:

```
assert_eq!(computed_value, 7)
```

Write this (running the fix command will auto fix the number in code):

```
expect!["7"].assert_debug_eq(computed_value);
```

Oh, you've got multiple test cases? No worries!

```
fn my_gas_test(#[values(2, 3)] gas_price: u8) {  
    let result = execute_tx(gas_price).gas_price;  
    if gas_price == 2 {  
        expect!["18"].assert_debug_eq(result);  
    } else {  
        expect!["27"].assert_debug_eq(result);  
    }  
}
```

Wait, the expected output is in a file? No problem!

```
expect_file!["path_to_file.txt"].assert_debug_eq(computed_value);
```

Call For Action! 📣 🧠

Remember that time you were copy-pasting expected values into a test, while quietly wondering why you spent 4 years studying for this?

Do your teammates a favor—go fix this code now!
